The ESTER code

Project Description

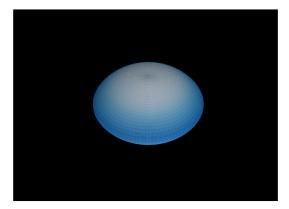

The ambition of this project is to set out a two-dimensional stellar evolution code, which fully takes into account the effects of rotation, at any rate and in a self-consistent way.

The difficult, but important point is that rotating stars are spheroidal and are never in hydrostatic equilibrium. They are pervaded by flows everywhere, even in the stably stratified radiative regions. These flows are essentially convective flows in thermally unstable regions (convection zones) and baroclinic flows in the radiative regions. These latter flows are grosso modo a differential rotation and a meridional circulation, with likely

Next :

- Implement nuclear evolution on MS
- Implement thermal evolution (PMS and post-MS)

Thermal Evolution : How to implement

We consider an isothermal atmosphere, which is cooling in some prescribed way. **The problem is 1D**

$$\rho \frac{\partial v_z}{\partial t} = -\frac{\partial P}{\partial z} - \rho g$$

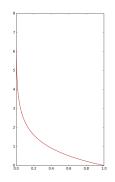

Assumptions : \vec{v} small and viscosity negligible.

 $P = R_*T\rho$ with $T \equiv T(t)$ prescribed

Hydrostatic solution is

$$\rho = \rho_0 e^{-z/a}$$

where
$$d = R_*T/g$$
 is the scale height.

Thermal Evolution (2)

Atmosphere evolution is through ρ_0 . How do we get it ?

The mass of the atmosphere is constant and so is its surface density Σ . This determine the evolution of ρ_0 , namely

$$\Sigma = \int_0^\infty \rho(z) dz = \rho_0 d \tag{3}$$

since $d(t) = R_*T(t)/g$ is known.

What about the velocity?

We start with masse conservation

$$\frac{\partial \rho v_z}{\partial z} = -\frac{\partial \rho}{\partial t}, \quad \text{with} \quad \rho = \rho_0 e^{-z/d}$$

or

$$\frac{\partial \rho v_z}{\partial z} = -\rho_0 e^{-z/d} \left(\frac{\dot{\rho}_0}{\rho_0} + \frac{\dot{d}z}{d^2} \right)$$

However

$$\frac{\dot{\rho}_0}{\rho_0} + \frac{\dot{d}}{d} = 0$$

After some calculation we find :

$$v_z = \frac{\dot{d}}{d}z$$

where we used the boundary condition $v_z(0) = 0$.

・ロト ・ 同ト ・ ヨト ・ ヨト

We now consider a self-gravitating sphere of gas of uniform temperature. This is a polytrope $n = \infty$. The evolution of temperature is supposed to be known. We need to solve :

$$\frac{1}{r^2}\frac{d}{dr}\left(r^2\frac{d\phi}{dr}\right) = 4\pi G\rho$$
$$-\frac{dP}{dr} - \rho\frac{d\phi}{dr} = 0$$
$$P = c^2\rho$$

where $c^2 = \mathcal{R}_* T(t)$ is the isothermal sound speed.

< ロト < 同ト < ヨト < ヨト

The spherical case

Hydrostatic equilibrium gives :

$$\rho = \rho_c \exp\left(\frac{\phi_c - \phi}{c^2}\right) \tag{4}$$

< ロト < 同ト < ヨト < ヨト

and

$$\frac{1}{r^2}\frac{d}{dr}\left(r^2\frac{d\phi}{dr}\right) = 4\pi G\rho_c e^{-(\phi-\phi_c)/c^2}$$
(5)

This equation gives the dependence $\phi \equiv \phi(\rho_c)$ and ρ_c comes from

$$M = 4\pi\rho_c \int_0^\infty e^{-(\phi-\phi_c)/c^2} r^2 dr$$

M is the total mass. Now ρ is known everywhere.

Since the evolution of density is known, we deduce the velocity field that ensures mass conservation

$$\operatorname{Div}(\rho \vec{v}) = -\frac{\partial \rho}{\partial t} \longleftrightarrow \frac{1}{r^2} \frac{\partial r^2 \rho v}{\partial r} = -\frac{\partial \rho}{\partial t}$$
$$v(r) = -\frac{1}{r^2 \rho} \int_0^r \frac{\partial \rho}{\partial t} x^2 dx$$

・ロト ・ 同ト ・ ヨト ・ ヨト

We wish to solve

$$\begin{cases} \partial_t \rho + \partial_z (\rho v_z) = 0\\ \partial_z P + \rho g = 0\\ \partial_t T = \kappa \Delta T - (P/\rho c_v) \partial_z v_z\\ P = \mathcal{R}_* \rho T \end{cases}$$
(6)

イロト イヨト イヨト イヨト

크

The algorithm with the cartesian case

$$\begin{cases} \partial_z (\rho_n v_n^z) = -(\rho_n - \rho_{n-1})/\delta t \\ \partial_z P_n + \rho_n g = 0 \\ \kappa \Delta T_n - (P_n / \rho_n c_v) \partial_z v_n^z = (T_n - T_{n-1})/\delta t \\ P_n = \mathcal{R}_* \rho_n T_n \end{cases}$$
(7)

ヘロト 人間 ト 人間 ト 人間 トー

which can be formally written

$$\vec{F}(\vec{X}_n) = \vec{b}_{n-1}$$

which can solved by a Newton-Raphson solver as the steady equation that have to be slightly modified.

Let us consider a simplified version first.

$$\varepsilon_{\rm CNO} = 8.67 \, 10^{27} g \rho X X_{\rm CNO} T_6^{-2/3} e^{-152.28/T_6^{1/3}} \, {\rm cgs}$$

During the pp or CNO cycles, protons are converted into He and this release

$$Q = (4m_{\rm H} - m_{\rm He})c^2 = 4.3 \times 10^{-12} J$$

so that

$$\frac{dX}{dt} = \frac{4m_{\rm H}\varepsilon}{Q} = -K\rho XX(^{14}N)T_6^{-2/3}e^{-152.28/T_6^{1/3}}$$

< ロト < 同ト < ヨト < ヨト

1D model : Nuclear evolution

 $\begin{cases} \partial_r P + \rho \partial_r \phi = 0 \\\\ \Delta \phi = 4\pi G \rho \\\\ \text{Div}_{\chi} \vec{\nabla} T + \varepsilon(\rho, T) = \rho T(\partial_t s + V \partial_r s) \\\\ \partial_t X + V \partial_r X = -X \rho X(^{14}N) T_6^{-2/3} e^{-152.28/T_6^{1/3}} \\\\ \partial_t \ln \rho + V \partial_r \ln \rho = -\partial_r (r^2 V)/r^2 \\\\ P = P(\rho, T, X, Z), \qquad \chi \equiv \chi(\rho, T, X, Z) \end{cases}$ (8)

1D model : Nuclear evolution

$$\partial_r P_n + \rho_n \partial_r \phi_n = 0$$

$$\Delta \phi_n = 4\pi G \rho_n$$

$$\delta t(\operatorname{Div}_{\chi} \vec{\nabla} T_n + \varepsilon(\rho_n, T_n) - \rho_n T_n V_n \partial_r s_n) = (\rho T)_n (s_n - s_{n-1})$$

$$\delta t(V_n \partial_r X_n + X_n \rho X(^{14}N) T_6^{-2/3} e^{-152.28/T_6^{1/3}}) = X_n - X_{n-1}$$

$$\delta t(V_n \partial_r \ln \rho_n + \partial_r (r^2 V_n)/r^2) = \ln \rho_n - \ln \rho_{n-1}$$

$$P \equiv P(\rho, T, X, Z), \qquad \chi \equiv \chi(\rho, T, X, Z)$$
(9)

We note that in the 1D-problem, $\delta t V = \delta \xi$, namely the displacement during δt solely comes into play.

• □ ▶ • 4 □ ▶ • Ξ ▶

The foregoing equation generalize immediately in 2D. But there is the question of the angular momentum evolution.

In steady case this is determined by

$$s\frac{\partial\Omega^2}{\partial z} = \frac{(\vec{\nabla}P \wedge \vec{\nabla}\rho)_{\varphi}}{\rho^2}$$

 $\operatorname{Div}(\rho s^2 \Omega \vec{w}) = \operatorname{Div}(\mu s^2 \vec{\nabla} \Omega)$ and $\operatorname{Div}(\rho \vec{w}) = 0$

ヘロト ヘヨト ヘヨト ヘヨト

2D model : Angular momentum evolution

Time-evolution of the local angular momentum needs to be taken into account.

$$\partial_t \vec{v} + \vec{\omega} \wedge \vec{v} = -(\vec{\nabla}P)/\rho - \vec{\nabla}\phi + \vec{F}_{\rm visc}$$

the φ -component gives :

$$\partial_t(\rho s^2 \Omega) + \text{Div}(\rho s^2 \Omega \vec{w}) = \text{Div}(\mu s^2 \vec{\nabla} \Omega)$$

while

$$\frac{\partial \omega_{\varphi}}{\partial t} + \overrightarrow{\mathrm{Rot}}(\overrightarrow{\mathrm{Rot}}\vec{w} \wedge \vec{w})_{\varphi} - s\frac{\partial \Omega^2}{\partial z} = \frac{(\vec{\nabla}\rho \wedge \vec{\nabla}P)_{\varphi}}{\rho^2} + \overrightarrow{\mathrm{Rot}}\vec{F}_{v}|_{\varphi}$$

イロト イポト イヨト イヨト

At first order we may say that

$$-s\frac{\partial\Omega^2}{\partial z} = \frac{(\vec{\nabla}\rho \wedge \vec{\nabla}P)_{\varphi}}{\rho^2}$$

and

$$\partial_t(\rho s^2 \Omega) + \text{Div}(\rho s^2 \Omega \vec{w}) = \text{Div}(\mu s^2 \vec{\nabla} \Omega)$$

イロト イポト イヨト イヨト

2D angular momentum evolution : Conclusion

The local time-evolution of angular momentum changes the meridional circulation that must adapt to the change of density. Hence

$$\rho \vec{w} \cdot \vec{\nabla} (s^2 \Omega) = F_v(\Omega) - \rho \partial_t (s^2 \Omega)$$

and

 $\operatorname{Div}(\rho \vec{w}) = -\partial_t \rho$

But there is a subtlety :

What about the grid velocity ? In 1D lagrangian models the velocity of the fluid \equiv the velocity of the grid.

ESTER is a bit lagrangian because the grid follow the surface and the interfaces...

イロト イヨト イヨト イヨト
